ISTA 130 SocialPerson Worksheet

This worksheet is about designing a class, specifically the `SocialPerson` class. Each instance of `SocialPerson` will represent a person and his/her social connections. It will contain the name of the person in an instance variable called `my_name` and a dictionary that maps the person's friends to the amount of time they have known each other. Define a class called `SocialPerson` and inside the class:

1. Define the `__init__` method. This method will have 3 parameters. As with all instance methods, the first parameter will be `self`. The second represents the person's name. Assign this parameter to an instance variable called `my_name` (don't forget to include `self.` to tell Python that this is an instance variable). The last argument will be a dictionary that has the names of friends as keys and the time the person has known them as values. Assign this parameter to an instance variable called `friends`.

2. Define the `__repr__` method. `self` is the only parameter in this method definition. This method should return a string with first line `"Friends of "` followed the contents of `my_name`, a line with 20 asterisks, and each of the keys in `self.friends`, one per line, indented two spaces.

3. Write a method called `new_year`. `new_year` has only one parameter, `self`, and increments the value associated with each key in `self.friends`.

4. Write a method called `add_friend`. `add_friend` has three parameters, `self`, `friend`, and `time`. `friend` is another instance of `SocialPerson`. This method adds the name of `friend` to `self.friends` as a key, with associated value `time`.

5. Write a method called `unfriend`. `unfriend` has two parameters, `self` and `sp`. `sp` is another instance of `SocialPerson`. This method pops the name of `sp` from `self.friends`.
