ISTA 130 Traversing Dictionaries Worksheet

Write a function called `pop_empty`. This function takes a dictionary as an argument. It traverses the dictionary, popping (removing) any key-value pair where the value is the empty list. Do NOT alter the dictionary as you traverse it.

Write a function called `reverse_dict`. This function takes a dictionary as an argument. It returns a dictionary that maps each value in the original dictionary to a list of the original keys that mapped to it. E.g., if the forward dictionary is `{'cat':'dog', 'rabbit':'dog'}`, the function returns `{'dog':['cat', 'rabbit']}`. Draw your own examples to understand this question!
