ISTA 130 Zoo II Worksheet

Define a class called `Zoo`. `Zoo` has two instance variables, both dictionaries. The first dictionary, `self.animals`, holds all of the animals in the zoo and maps their names to their `Animal` objects. The second, `self.food`, maps food names to `Food` objects. The `Zoo` initializer will build each of these dictionaries from files and takes two arguments – the animal file name and the food file name. Both files are csv files. Textual representations of `Animal` objects are stored one per line in the following format:

```
<name>,<species>,<food>,<amount>
```

When adding a name-`Animal` pair to `self.animals`, ensure that the name is unique by adding `'-2'` to it if already exists as a key until it is unique. `Food` objects are stored in the food file in the following format:

```
<name>,<price>,<qoh>
```

Write a method called `reorder`. It takes one argument, a `Food` object. It determines if the amount on hand of that type of food is enough to feed all of the animals that eat that kind of food in the zoo for at least 7 days. If not, it returns the amount necessary to feed all of the animals in the zoo that eat that food for 30 days. If so, it returns `None`.

Write a method called `get_order`. `get_order` builds and returns a dictionary of orders for each type of food. It maps the name of each food to the amount that needs to be ordered as determined by `reorder`.
