ISTA 130 Extra Credit Worksheet Week 6

1.) Write a Boolean *expression* that evaluates to **`True`** if the value of the variable **`count`** is between 1 and 10 inclusive.

2.) How does Python know to which **`if`** an **`else`** belongs? As for example in this:

```
if name == "Snoopy":
   if color == "white":
      print("Yep, Snoopy")
   else:
      print("Nope, imposter")
```

3.) Write a conditional statement that sets the value of a variable named **`answer`** to 1 if a variable named **`result`** is equal to 100. Set **`answer`** to 2 otherwise.

4.) Write a conditional statement that sets the value of a variable **`gradepoint`** to 4 if a variable named **`score`** is 90 or above, 3 if **`score`** is at least 80 and less than 90, 2 if **`score`** is at least 70 and less than 80, 1 if **`score`** is at least 60 and less than 70, and 0 otherwise.

5.) A fruit company sells oranges for 32 cents a pound plus $7.50 per order for shipping. If an order is over 100 pounds, shipping cost is reduced by $1.50. Write a function that will take the number of pounds of oranges as a parameter and **`return`** the cost of the order.

6.) Write a function that takes three integers as parameters and returns the largest.

7.) Write a function that takes two parameters, a pay rate and the number of hours worked, and returns the pay. Any hours over 40 are paid at time and a half.

8.) What is the output of the following code?

```
weight_oz = 1.5
length = 28

if weight_oz <= 1.0:
  price = 0.45
elif weight_oz <= 2.0:
  price = 0.65
else:
  price = 1.05

if length > 10:
  price = price + 0.25
if length > 20:
  price = price + 0.50
if length > 30:
  price = price + 1.00

print("Price is: $", str(price))
```
